

This image explores the interplay between angle and colour, using light as a medium of contrast and convergence. Two sunglasses are placed back to back, illuminated from opposing directions: a soft red light from the upper left and a bright blue light from the front right. Their angled intersection creates a vibrant purplish overlap at the center, where warmth and coolness meet in chromatic tension. The resulting shadows are equally balanced, forming a visual harmony. This composition reflects how opposing forces in temperature, direction, and tone can coexist and merge, demonstrating light's power to both divide and unify.

This image explores intensity and angle through dramatic contrast and simple expression. The low-angle white light clearly illuminates the front sunglasses, making them visible. Behind them, the second pair of sunglasses are partially hidden, revealed only by subtle angular reflections off the surface of the model box. From the center to the borders, the light gradually fades, creating a visual gradient. By adjusting the distance between the flashlight and the model box, I controlled the intensity of the focus to enhance the spatial depth. A mysterious cinematic atmosphere is created where the light guides the viewer through layers of visibility and suggestion.

This work explores the intersection of color, angle and intensity, using snacks in transparent packaging to create the confined atmosphere of a campfire. A warm internal light source is placed in the snack pile, creating an amber glow that mimics the light of an internal fire. Distant and diagonally placed cool blue light is subtly reflected on surfaces, enhancing the sense of realism and depth. Shadows created on the walls of the model box resemble flickering flames. The project investigated how multiple angles of light sources and contrasting color temperatures can mimic natural phenomena and produce immersive spatial emotions.

This work investigates light intensity, color change and refraction in water and pigmented media. An acrylic transparent box filled with colored water was placed inside the model box, while a horizontal white light beam was projected on a tabletop. As the beam passes through the colored liquid, it creates a soft, moving projection on the wall - the light is colored by the pigment and regulated by the movement of the water. Water is a sensitive medium for controlling intensity, allowing for subtle changes through flow and refraction, making transitions feel more natural and atmospheric. This work reflects how suspended materials and fluid optics can make space ephemeral, unstable and vivid.

This work uses the interplay of color, angle and surface reflection by arranging discarded coffee capsules wrapped in foil. The capsules are loosely dispersed on the tabletop, creating an irregular topography of metallic curves and textures. Colored light from multiple directions (above, below, and to the sides) was introduced to activate the reflective surfaces. As a result, light refracts and reflects unpredictably, producing areas of mixed hues, saturation gradients, and color distortion. The use of foil creates a fragmented lightscape in which color and intensity become unstable, emphasizing how irregular materials and multiple angles of light can transform the most mundane objects into immersive spatial compositions.

This work investigates diffuse reflection through the interplay of texture, material absorption and soft lighting. A stuffed bear is placed in a white model box on a black non-woven base. A soft overhead light casts light onto the bear's fur, which is scattered and absorbed by thousands of fine fibers, creating an ambient rather than directional light. The black base prevents secondary reflections, enhances contrast and anchors the figure. The resulting space is defined not by brightness but by softness and emotional inclusion, where light no longer defines edges but blurs and soothes them.
